The cytochrome P-450 (CYP) system is one of the most important systems for drug metabolism. Approximately 60% of all clinically prescribed drugs are metabolized via CYP3A4.

Cannabinoid products can be inducers or inhibitors of the various CYP enzymes; therefore, healthcare providers should consider monitoring patient's use of cannabis products to reduce the risk of adverse events and to maintain the effectiveness of other concomitant medications.

Based on the 4 FDA-approved cannabinoid drugs, CBD and THC may have the following side effects and drug-drug interactions.

CBD is a substrate for CYP3A4 and CYP2C19. Therefore, drugs that inhibit or induce these 2 enzymes will affect the plasma concentration of CBD. CBD can function as an inhibitor, an inducer, or both.

<table>

THC is a substrate for CYP3A4 and CYP2C9. Therefore, drugs that inhibit or induce these 2 enzymes will affect the plasma concentration of THC.

THC is highly protein bound. May displace other drugs, increasing the risk of adverse events.

- Added CNS effects (dizziness, sedation, confusion) when taken with CNS depressants
- Hypotension, hypertension, and tachycardia may occur when taken with drugs that also affect the cardiac system.
- THC may lower seizure threshold. May affect anticonvulsants therapy.

Potential drug interactions may occur with CBD and/or THC and the following medications:

- Proton pump inhibitors
- Antibiotics
- Antidepressants
- Anticonvulsants
- Antifungals
- Antivirals
- Induction/anesthesia
- Antihypertensives
- Antihypertensives
- Antipsychotics
- Benzodiazepines
- Chemotherapy
- Opioids
- Sympathomimetics
- Anticoagulants
- Antiplatelets
- Others

Monitoring for safety and effectiveness is recommended.

Advise patients to talk to their healthcare providers about their current medications and OTC products they are taking at their next visit.

Pharmacists should talk to their patients at their next visit about possible drug interactions with concomitant cannabinoid therapy.
